Chapter 1

Encoding Locations

1.1 Introduction

Encoding of locations has historically been of great importance, and is always being modernized. This chapter explains the general definition of locations, which types of locations are important for this project, and how to represent these locations so that they are universally interpretable and do not rely on a postal code system.

1.2 A Brief History Of Geographic Locations

A location is roughly described as a place or position. Throughout history, various navigational techniques and tools like the sextant, nautical chart and marinner's compass were used, measuring the altitude of the North Star to determine the latitude ϕ , in conjunction with a chronometer to determine the longitude λ of a location on the Earth's surface. The combination of coordinates is a distinct encoding of a location. This particular system is still commonly used today.

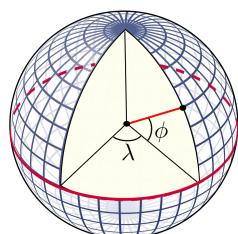

Fig. 1.1 A perspective view of the Earth showing how latitude and longitude are defined on a spherical model.

The history of this encoding goes way back to when it was first proposed in the 3rd century BC by Eratosthenes. He invented the discipline of geography, and was known for also being the first person to calculate the circumference of the Earth with remarkable accuracy. Today, navigation relies on satellites that are capable of providing information to determine a location with a precision of 9 meters. Hybrid methods using cell towers, Wi-Fi Location Services, and the new Galileo global navigation satellite system, provide tracking with a precision down to the metre range. These locations are ordinarily communicated using the same established latitude and longitude encoding. For a human being, it is not practical to exchange day-to-day locations as geographical coordinates. For that, addresses much more suitable, but can be ambiguous, imprecise, and inconsistent in format. Addresses commonly make use of Postal Code systems, which have reliably been assigned to geographical areas with the purpose of sorting mail. Although even today, there are countries that do not have a Postal Code system. This forces the legacy system to support addresses for the fixed pricing functionality as well. In contrast to the geographic coordinate system, postal codes describe streets and areas of varying shapes and sizes. A location being roughly described as a place or position, can be decomposed as an abstract term to describe physical or imaginary areas with varying radiuses and shapes. You could prepend 'the location of' to the following terms as an example: America, the birthplace of Sokrates, Wall Street, the center of the universe, the Laryngeal Nerve of the Giraffe, churches in the Netherlands. The final example presents the main challenge of this project, how to communicate the location of a collection with points or areas of differing shapes and sizes that may overlap?

1.3 Requisite Location Types

While setting up a backlog for a project, a shared knowledge about the terminology used in the issues must be achieved in order to collaborate effectively. Words or symbols do not have an absolute meaning, and ambiguity of abstract linguistic terms should be elucidated. In section 3.2.1 of Appendix ??, an agreement was made on what the terms "area" and "point" meant. During the process of implementing TPS, the definitions of a location have been refined.

1.3.1 The Point

A point is a unique place expressed as a distinct coordinate pair. An address in the legacy system could be translated to a point. For example, the address that is tied to Schiphol arrival is: Aankomstpassage, 1118 AX Schiphol Centrum. The point that encodes this location is

(52.308891, 4.760900). This location is contained in the set of all possible points on Earth, which could be expressed using set builder notation:

$$P = \{(\phi, \lambda) \in \mathbb{R}^2 \mid -90 < \phi < 90, -180 < \lambda < 180\}$$

$$(52.308891, 4.760900) \in P$$

A point itself can not be used to match whether another point is contained within it, because the probability of a match is infinitesimal. Only when decimals were disregarded to decrease the precision of a point it would be possible, in which case it would still not be useful in this application, because the imprecise point would be a square.

1.3.2 The Area

An area is a set of points with an infinite granularity. This definition allows for an area to have holes inside them, consist of other locations and contain other locations, and be infinitely precise. The most useful property of this area is to check whether a point is contained within the area, or which areas contain a given point. For this to be the case, the points must be packed together as it would form a shape. This definition, however conceptually valuable, will not be of much practical use. For example, P is an infinitely long set of coordinates, an area that represents the earth's surface. If ϕ ranged between 0 and 90, the set could describe all points located in the northern hemisphere, but would still be infinitely long. Checking whether a given point is contained by checking an infinite amount of real number pairs will take an infinite amount of time in the worst case scenario. An area can be described as a subset of all points:

$$a_1 \subseteq P$$

The set of all possible areas can be defined by the power set of P :

$$A = \mathcal{P}(P)$$

such that a subset of points, called an area, is in all possible areas A :

$$a_1 \in A$$

At the equator, 1 degree is 111320m, so 0.000001 degrees is around 11cm. Six decimal places will be sufficient for location matching for this application. But even when reducing coordinates to having six decimal places, it would be impractical. For this reason, it is

more realistic to only describe the rough edges of an area using a polygon shape. Instead of checking for a single point in a non-terminating iteration over all points in an area, a mathematical calculations could be used to check whether a unique point is contained within the polygon.

1.3.3 Postal Codes, Addresses, and Polygons

All postal codes that start with a ten describe the city of Amsterdam, the entire area of Amsterdam can be drawn as a big polygon containing all the postal codes that start with a ten. In reverse, this procedure would not work. If a polygon was drawn cutting Amsterdam in half diagonally, a single postal code pattern would never be flexible or precise enough to be able to describe the boundaries of the polygon. One big taxi company making use of taxiID's legacy system is located in the United Arab Emirates. This company would not be able to convert anything at all, because the United Arab Emirates does not have a postal code system to begin with.

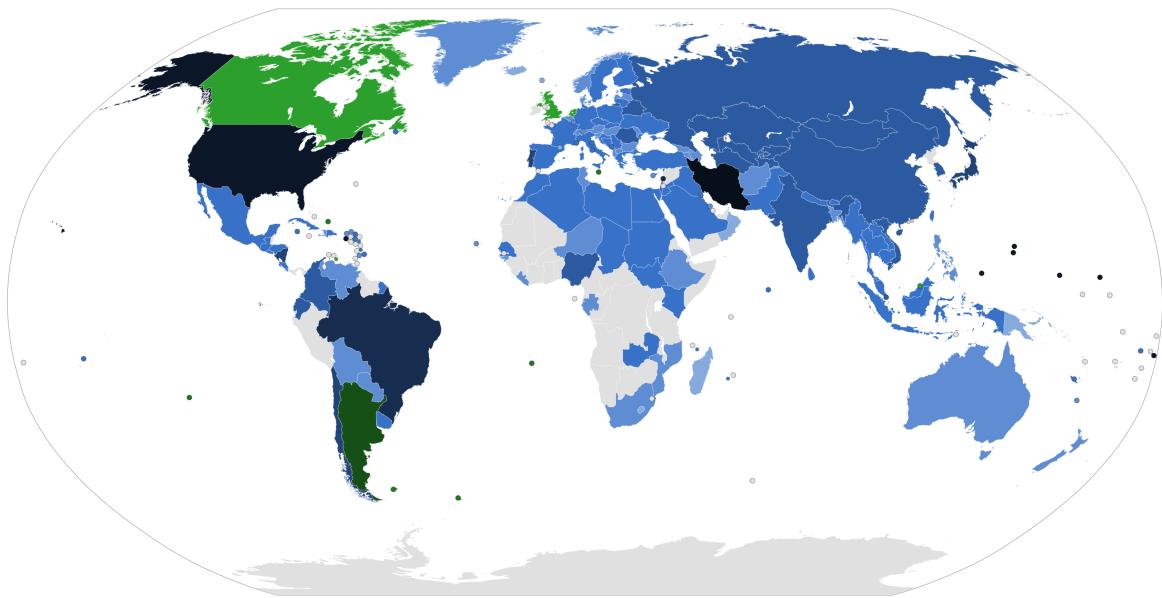

Fig. 1.2 Postal codes by country with amount of digits ranging from three digits (lightblue) to eight digits (darkgreen) and no postal code system (gray).

When a trip is booked in the United Arab Emirates, the only information provided as a destination or departure location are geospatial coordinates and addresses. These addresses are compared with long lists of matching addresses in the legacy database, as previously described with postal codes. Addresses and postal code systems do not provide universally interpretable and precise encodings of locations, especially for the locations that matter for

this project: points and areas. Addresses can be ambiguous, addresses and postal codes can be imprecise, postal codes are not uniform, and some countries do not have a postal code system. In contrast, polygons would provide unique and precise location definition that is uniform and universal. But postal codes and addresses have been useful in the legacy system. When moving to other encoding techniques, this usefulness must be preserved.

1.3.4 Location Matching

If the following statements are true for a given location encoding, the location encoding is useful and able to operate independently from the postal code and address systems.

1. Every location is stored in a database as a single entity
2. Locations can consist of multiple locations (see figure ??)
3. A deterministic predicate of whether a location is fully contained within a location is achievable
4. A deterministic method of finding all locations containing a single location can be used
5. A method of determining precedence of location in case of overlap must always yield one result, and discard all others

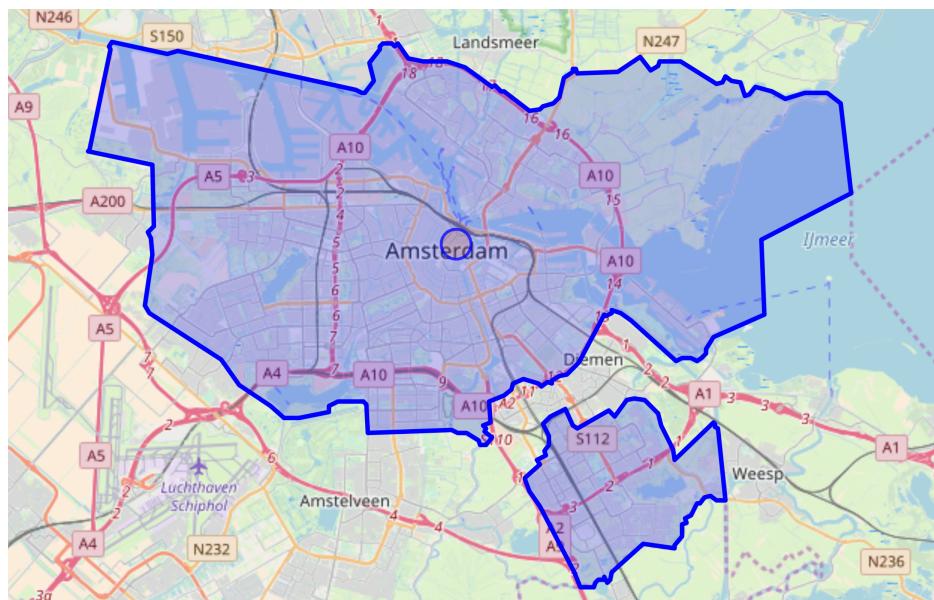

Fig. 1.3 Amsterdam - A single location contrived of multiple locations.

1.4 Literature Review

Many spatial database systems support a basic Geometry hierarchy of Points, Polygons, MultiPoint and MultiPolygon Classes, as described in the OGC [?] and ISO 19125 [?] standard.

Clustering

What 3 words, a multi-award winning global addressing system, bases 3m x 3m squares, covering the planet, on a combination of three words.

If a radius was assigned to the centroid of the shape that is formed by the boundaries of the street, neighbourhood, province or country.

Geospatial

Postal code

kks32: See if other people solved locations

1.5 Database Prerequisites

The database must be capable of determining whether a virtual perimeter contains a set of coordinates, more specifically, it must adhere to The Open Geospatial Consortium (OGC) Simple Feature Access ISO 19125-1 [?] and ISO 19125-2 [?], including spatial data types, analysis functions, measurements and predicates for this requirement. The scenario presented in image ?? should be replicable.

1.5.1 OpenGIS Compatible databases

MYSQL's innate integrity is a good reason to opt for a full MYSQL database setup. MariaDB is a fork of MYSQL that performs better according to benchmarks, however they don't always translate to real life situations. It's easy to migrate from MYSQL to MariaDB, so choosing MYSQL at first could be preferable as an instance of MYSQL is already used at TaxiID. PostgreSQL offers a spatial database extender for that is OpenGIS compliant called PostGIS that adds support for geographic objects and location queries.

All spatial data types inherit properties such as type and spatial reference identifier (SRID). For rigorous documentation, both PostGIS documentation [?] and MYSQL documentation [?] could be consulted. When a generic geometry column, or point column is created, points can be inserted as shown in snippet ?? and ??

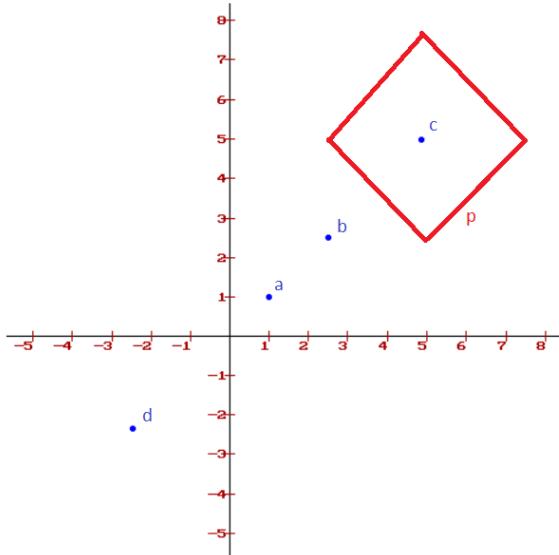

Fig. 1.4 Four Points, one Polygon p containing Point c.

```

1 START TRANSACTION;
2 SET @a = ST_GeomFromText('POINT(1 1)');
3 INSERT INTO point (point) VALUES (@a);
4 SET @b = ST_GeomFromText('POINT(2.5 2.5)');
5 ;
6 INSERT INTO point (point) VALUES (@b);
7 SET @c = ST_GeomFromText('POINT(5 5)');
8 INSERT INTO point (point) VALUES (@c);
9 SET @d = ST_GeomFromText('POINT(-2.5 -2.5)');
10 ;
11 INSERT INTO point (point) VALUES (@a);
12 # also insert @b, @c, and @d
13 COMMIT;
```

Listing 1.1 Insert four points

```

1 START TRANSACTION;
2 # First and last point must be the same
3 SET @a = PolygonFromText('POLYGON((2.5 5,5
4 7.5,7.5 5,5 2.5,2.5 5))');
5 INSERT INTO polygon (polygon) VALUES (@a);
6 COMMIT;
```

Listing 1.2 Insert polygon

It is evident that c is contained in p. To determine which points are contained in p, the function as seen in Snippet

kks32: Add ref to snippet

can be used, which returns the point with coordinates [5, 5] as expected.

```

1 // All points contained in polygon
2 SELECT ST_ASTEXT(POINT)
3 FROM POINT
4 WHERE
5 ST_CONTAINS(
6   (
7     SELECT POLYGON
```

```

8   FROM POLYGON
9   WHERE id = 1
10  ),
11  POINT
12 )
```

Listing 1.3 Select points contained in polygon

```

1 // All polygons containing point
2 SELECT ST_ASTEXT(POLYGON)
3 FROM POLYGON, POINT
4 WHERE
5   POINT.id = 3 AND ST_CONTAINS(
6     POLYGON.polygon,
7     POINT.point
8   )

```

Listing 1.4 Select polygons containing point

1.5.2 OpenGIS Incompatible databases

MongoDB doesn't offer OpenGIS implementations but has geospatial query operators that may provide enough functionalities for current requirements

kks32: Add ref to Geospatial Query Operators — MongoDB Manual 3.6

. The argument for choosing one over the other depends on the vast differences between SQL and NoSQL, next to performance and extensiveness of geospatial features. The setup displayed in image

kks32: Add ref to image

is recreated in MongoDB using queries shown in snippet

kks32: Add ref to snippet

```

1 db.point.insertMany([
2   { shape: { type: "Point", coordinates: [1,
3     1] } },
4   { shape: { type: "Point", coordinates:
5     [2.5, 2.5] } },
6   { shape: { type: "Point", coordinates: [5,
7     5] } },
8   { shape: { type: "Point", coordinates:
9     [-2.5, -2.5] } },
10  })
11
12  db.polygon.insert({
13    shape: {
14      type: "Polygon",
15      coordinates: [ [ [2.5, 5], [5, 7.5], [7.5,
16        5], [5, 2.5], [2.5, 5] ] ]
17    }
18  })
19
20  db.point.createIndex({ 'shape': '2dsphere'
21    })
22  db.polygon.createIndex({ 'shape': '2
23    dsphere' })

```

```

// All points contained in polygon
var p = db.polygon.find({})

db.point.find({
  shape: {
    $geoWithin: {
      $polygon: [
        [2.5, 5],
        [5, 7.5],
        [7.5, 5],
        [5, 2.5],
        [2.5, 5]
      ]
    }
  }
})

// All polygons containing point
var p = db.point.findOne({ coordinates:
  [5, 5] })

db.polygon.find({
  shape: {

```

Listing 1.5 Select points contained in polygon

```
23 $geoIntersects: {  
24   $geometry: {  
25     type: "Point",  
26     coordinates: [5, 5]  
27   }
```

```
28 }  
29 }  
30 })
```

Listing 1.6 Select points contained in polygon

Next to database solutions for this requirement, services exist that are capable of geofencing. Although these services may not be free, and the added dependencies restrict extensibility.

1.6 Performance and Clustering Trade-offs

Agarwal and Rajan state that NoSQL take advantage of cheap memory and processing power, thereby handling the four V's of big data more effectively, but lack the robustness over SQL databases

kks32: Add reference to Agarwal and Rajan

. The report dives deeper into spatial queries and concludes that their tests suggest that MongoDB performs better by an average factor of 10, which increases exponentially as the data size increases, but lack many spatial functions that OpenGIS supports. Although improvements have been made

kks32: Add reference to Geospatial Performance Improvements in MongoDB 3.2," MongoDB

after the cited paper Schmid et al. 2015

kks32: Add ref to Stephan Schmid Eszter Galicz

was published. The team argues that clustering is much easier in MongoDB, which may be important in the future when the company grows. As the required functionalities exist in both SQL and NoSQL, it is beneficial to opt for MongoDB for its performance and alignment with the teams experience. Although if robustness is desired, or extra GIS functionalities required, SQL should be taken into consideration.
